STATEMENT OF SOURCES

DECLARATION

I declare that this thesis is my own work and has not been submitted in any form for another degree or diploma at any university or other institution of tertiary education. Information derived from the published or unpublished work of others has been acknowledged in the text and a list of references is given.

________________________________________  ________________________
Signature                                      Date
STATEMENT OF CONTRIBUTIONS

General contributions towards this study included:

- International Postgraduate Research Scholarships (IPRS)
- James Cook University Postgraduate Research Scholarships (JCUPRS)
- Pmd*CRC Top-up Scholarship
- Pmd*CRC educational and training fund

Contributions from others towards this thesis are clearly stated at the forefront of each chapter where applicable. A summary of the major contributions is also provided here:

- **Chapter 4**: Dr. J. G. McLellan – 2D Numerical modelling of the Century deposit and text.

- **Chapter 5**: Dr. J. G. McLellan – 3D Numerical modelling of the Century deposit and text.

- Normal supervisory condition throughout the preparation of the thesis included discussions and proofreading by Prof. N.H.S. Oliver (all thesis), and Dr. J.G. McLellan (Chapters 4, 5).
Acknowledgements

I acknowledge Prof. Nick Oliver for his constant enthusiasm and encouragement, demonstrated throughout the accomplishment of this project. A special thanks goes also to John McLellan for his collaboration and for the numerous discussions that helped the development of a significant component of this thesis. Lucy Chapman is thanked for her support and interest in my progresses in relationship to the genesis of Century. I thank Ian Kelso, Tom Blenkinsop and Laurie Hutton for assistance in the fieldwork and related discussions concerning the geology of the Lawn Hill Region and the Century deposit. The entire Century Mine Zinifex Geological and Engineering staff is acknowledged for collaboration and help, in particular Paul Habermann, Mathew Clifford, Amanda Wass, Vicky Edge, Steve Havenaar, Rodney Henderson, Angela Lorrigan, and Patze Volker.

The author’s involvement in this project commenced in 2002 and was sponsored by an International Post Graduate Award, and a pmd*CRC top-up scholarship. As a student researcher of the pmd*CRC, the author was involved with the 11 Terrain Project (Western Fold Belt). The author benefited from this, having the opportunity to attend numerous meetings, conferences and training organised and sponsored by the pmd*CRC.

I am grateful to dad Gianni, mum Isabella, Martina and Susanna for their patience and support.
Thesis abstract

Quantitative analysis with the aid of numerical and computational modelling has been used to address geological problems since the 1940s. The number of applications developed and used to solve geological problems has increased largely because of the advent of desktop microcomputers. However, despite the introduction of mathematical-computational methods, the observational, inductive approach of Hutton and Wegner remains deep in the geological science.

Qualitative rather than quantitative geology has won in the past because of the naturalistic inclination of geologists - “rather than sit on their desk typing and modelling natural phenomena, they were more interested in exploring the world with the naked eye, spending their time conceptualising models and integrating the data collected in the field”.

With globalisation geologists have broadened their objectives as larger and numerous databases are available. Therefore, rather than collecting their own data, they now have new technologies to retrieve and process large databases. The drawback of this advantage is the lack of data quality verification, which can be a substantial problem. However, a statistical treatment of datasets can be a partial solution to this.
The author as a geologist felt the need of demonstrating that a quantitative-computer based description of a multivariate geological system could lead to a significant improvement of the understanding of such a system.

A line can be drawn to subdivide computational approaches that use inference networks based on physical laws (e.g. Geodynamic modelling) to bound variables, or empirical laws (e.g. Bayesian Probability Analysis) that are not characterised by the nature of the data (such as measures of spatial association). Alternative methods (e.g. Fuzzy Sets, Dempster-Shafer, Neural Networks) have been suggested to treat multivariate data less empirically.

A possible way to improve the quantitative analysis is the simulation of geological parameters (Chapter 4 – 5). The interaction between the geologist and the computer is iterative in this case – multiple simulation leads to a refinement of chosen approximation. Nevertheless, this methodology is often biased and arbitrary. The best approach perhaps remains the validation of computational models comparing them against the experimental results and observations.

The objective of this thesis was then to apply quantitative/computational tools to different geological scenarios in the Lawn Hill Region, Mount Isa Inlier. Part of this study focused on one of the largest Pb-Zn mineral resources in Australia, the Century zinc deposit. The objective of the first section of this thesis was to discover possible new mineral resources similar to the Century orebody, and comprehend how the mineral deposit formed.

Two case study applications to the Lawn Hill Region at regional and mineral deposit scale (Century deposit) are presented. The first study reflects the need of data
integration in a multivariate system to obtain a statistical estimate of the likelihood of finding a mineral deposit. The concepts of Bayesian reasoning were reviewed and a computer program (coded in Visual Basic) was developed to perform Bayesian modelling. The results were then compared against an expert-driven model to obtain a predictive map for the Lawn Hill Region. The analysis suggested that most of the mineral deposits/prospects are located where knowledge driven models favour the occurrence of SEDEX mineralisation. The data driven model suggests that other Pb-Zn deposits more likely are proximal to the Termite Range fault. Integration of KD and DD models suggests prospectivity for SEDEX-style mineralisation north of the Edith cluster a vein style ore.

The second study involved the quantitative 3D spatial analysis of the Century deposit. The 3D model of the mineral deposit was also combined with a 2D-3D coupled deformational and fluid flow simulation for the mineral deposit. The integration of these modelling tools allowed a better conceptualisation of the variables controlling the spatial distribution of base metals within the mineral deposit. In this case the research effort was directed toward the use of computational tools to solve the classical problem of understanding how the ore deposit formed. The results obtained support (re)mobilisation and a broad scale metal zoning similar to what is observed at Lady Loretta and HYC. Results also illustrated how basin compartmentalisation can control (re)mobilisation, fluid-flow and therefore how a mineral deposit evolves in time. A comparison between the different scale of zoning observed coupled with numerical 2D-3D results outlined that more likely Century is an exhalative system that however experienced later epigenetic introduction of base metals. Modelling results have in
general outlined that classification of geological patterns can be an effective way of discriminating the genesis of an ore deposit. For instance, the textural evolution of a mineral deposit which is derived from a combination of mechanical and chemical processes (the mechano-chemical coupling modelled by Ortoleva, 1994) may represent non-linear behaviour and lead to patterning of the geological system. In this context, the relationships observed and modelled between the evolution of permeability structure and the spatial distribution of mineral grades represent an example of how understanding the dynamics of complex system provides improved interpretations.

The third study, focused on the post-mineralisation Lawn Hill Megabreccia, and explores the variety of patterning of sedimentary textures and deformational features, aimed at differentiating the timing and origin of this brecciation event. The research combined qualitative and quantitative analysis of structural, sedimentary and stable isotopic features at various scales. The results indicate a synsedimentary (Cambrian) origin for the brecciation. However, the study has emphasised that different causative processes (e.g. tectonic, meteorite impacts) may lead to similar patterning.

To conclude, quantitative modelling of the presented geological examples suggests that we need to improve accuracy and numerical descriptions of the system to reveal the timing of formation and how a certain geological process occurred. In other words the loss of data induced by generalisation and oversimplification (often required in computational and quantitative modelling) can reduce the reliability of a predicted answer. Self-organisation and chaos theories (Synergetics) may be a new way to approach and describe the observed patterning of geological events and could be used
to provide better mathematical models to understand ore genesis, discover a mineral deposit or ascertain the origin of a catastrophic event.

Fig. 5.3 Mine stratigraphic column (Clifford and Kelso, 2003), showing alternating shale, siltstone intervals and relative total deposit, averaged, concentrations in weight % for Zn-Pb-Mn. Note higher Mn contents of siltstones between the Pb-Zn-rich shales.  

Fig. 5.4 3D structural and property model of the Century deposit.  

Fig. 5.5 S-Grid model conformed to the stratigraphic layers bounding the ore deposit.  

Fig. 5.6 Summary of the GoCAD model components, comprising a surface based structural framework where modelled properties were applied, and an S-grid model representing the 3D spatial distribution of base metals.  

Fig. 5.7 2D map views of base metal concentrations, Mn and thickness distributions over reconstructed surfaces representing mine stratigraphic intervals.  

Fig. 5.8 Summary of figures illustrating the relationship between faulting and mineralisation.  

Fig. 5.9 Diagram portraying examples of GoCAD spatial analysis of adjacent shale and siltstone layers (320-410, 420-430), used to estimate the degree of vertical redistribution of Pb and Zn.  

Fig. 5.10 Results from Fig. 5.9 obtained from correlation analysis, showing the areas where Zn-Pb redistribution occurred.  

Fig. 5.11 Spatial distribution of Zn-Pb-Mn at Century.  

Fig. 5.12 Diagram illustrating the likely effect of faulting and fluid flow in controlling the localisation of remobilisation and mobilisation of base metals during post-sedimentary deformation.  

Fig. 5.13 Conceptual model for syntectonic mineralization of the Century deposit.  

Fig. 5.14 Numerical results for the Century deposit incorporating the main features of the system.  

Fig. 5.15 Plot of pore pressure at around 3% bulk shortening.  

Fig. 5.16 Detail of part of Fig. 5.14b, showing fluid flow vectors in and around shales.  

Fig. 5.17 Schematic diagram illustrating the fluid flow variation during basin evolution,
and its influence on the type of metal zoning, which represents a constraint for the different ore genetic models. 5-50

Chapter – 6

Fig. 6.1 Map view of the study area. 6-7

Fig. 6.2 Simplified stratigraphy from south to north through the Amadeus, Georgina, Wiso and Daly Basins. 6-11

Fig. 6.3 Crustal transect showing the locus of reactivation during the Petermann and Alice Springs Orogenies. 6-12

Fig. 6.4 Photographic view and relative structural interpretation of the northern and eastern walls of the Century Mine. 6-25

Fig. 6.5 Examples of folding patterns observed in the Thorntonia Limestone. 6-27

Fig. 6.6 Landscape view of a depositional scar (black outline) truncating highly deformed layers of dolomitic grainstone superposed by flat laying unreformed strata. 6-28

Fig. 6.7 Conceptual models of slump fold development. 6-30

Fig. 6.8 Lithostratigraphic classification of the Lawn Hill Outlier. 6-32

Fig. 6.9 Examples of steep dipping intrusions in Middle Cambrian cover. 6-35

Fig. 6.10 Examples of interpreted solution/collapse cavities in cherty limestone exposed on the western side of the Century Mine. 6-36

Fig. 6.11 Breccia typologies observed along mine exposures, and also in drill core and outcrop, in the more internal part of the annulus. 6-37

Fig. 6.12 Slumping initiation in relatively undeformed beds of the Thorntonia limestones. 6-40

Fig. 6.13 Paragenetic chart illustrating the initial phases of basin evolution involving slump/scar development, the formation of different breccia types and their evolution. 6-45

Fig. 6.14 Mohr diagram of shear stress against effective normal stress, with a composite Griffith-Coulomb failure envelope for intact rock normalised to tensile strength. 6-49

Fig. 6.15 3D structural/CBX breccia model of the Century Mine. 6-51

Fig. 6.16 Stereoplots of fault planes proximal to voxels containing carbonate breccia. 6-54

Fig. 6.17 Palaeostress directions (eigenvectors/eigenvalues, e1, e2, e3) for the dip-classes considered in (a) D<30; (b) 30<D<60; (c) D>60 (Fig. 6.16). 6-55

Fig. 6.18 Examples of post-intrusion structural features. 6-60

Fig. 6.19 Stereoplots representing the preferential trend of distribution expressed in %

xx
area for the whole joints dataset.  6-62

Fig. 6.20 Map-view of the northwestern corner of the Century Mine illustrating transects where structural data were collected.  6-64

Fig. 6.21 Scanlines along transect 2 ordered from north to south.  6-66

Fig. 6.22 3D Block diagram representing a summary of the field relationships discussed in the text and presented in previous plates.  6-71

Fig. 6.23 Paragenetic reconstruction of the cross-cutting relationships used to reconstruct the temporal evolution of the sedimentary and tectonic events that contributed to the formation of the Lawn Hill Megabreccia.  6-75

Fig. 6.24 3D Block diagram illustrating the variation of depositional environments across the Lawn Hill Outlier.  6-77

Fig. 6.25 Examples of shatter cones collected in the Gum Hole Plain.  6-80

Chapter – 7

Fig. 7.1 Mandelbrot-set and relative enlargement views of smaller details on the edge of the Cardioid.  7-6

Fig. 7.2 Bifurcation diagram representing a change from a single state of equilibrium to two stable phases.  7-9

Fig. 7.3 Plots of logistic function for different values of (r).  7-12

Fig. 7.4 Perspective views of the Lorenz attractor in phase space.  7-13

Fig. 7.5 Schematic diagrams representing the basic rules that constrain the mineral system evolution.  7-18

Fig. 7.6 Diagram summarising distinctive patterns as a function of spatial location within an exhalative system.  7-21

List of tables

Chapter – 3

Table 3.1. Summary of the broad characteristics of SEDEX, IRISH-style and MVT deposits.  3-26

Table 3.2. Weights of evidence and relative variances s(W), Contrast (C), and studentised Contrast Cw for grouped, lithostratigraphic formations outcropping in the
Lawn Hill Region. 3-81

**Table 3.3.** Weights (W), contrast (C) and relative studentised values (Cw) for cumulative distances from linear and point patterns. 3-84

**Table 3.4.** Summary of contrast analyses for considered sub-classes of geophysical datasets. 3-85

**Table 3.5.** Predictor binary patterns and relative Weights of Evidence, variances and area proportions ranked by contrast (C). 3-87

**Table 3.6.** Comparison of CI results of chi-square pairwise evaluation against OT and NewOT tests. 3-103

**Table 3.7.** Omnibus and New-Omnibus test results for multiple combinations of evidential themes. 3-104

**Chapter – 4**

**Table 4.1.** Correlation of deformational history in three locations of the Mount Isa Block, including a summary of age dates from several locations. 3-12

**Table 4.2** Physical properties for materials, Models 1 and 2. 3-52

**Chapter – 5**

**Table 5.1.** Material properties for the geological units used in the numerical models. 5-41

**Chapter – 6**

**Table 6.1.** Bingham axial distributions for sills, oblique dikes, and sub-vertical dikes. 6-56

**Table 6.2.** Carbon and oxygen isotope analyses of whole rock and veins on the Thorntonia Limestone and Mesoproterozoic basement. 6-68
