RADIOWAVE PROPAGATION MEASUREMENTS AND PREDICTION IN BUSHFIRES

Thesis submitted by
Kgakgamatso Marvel MPHALE MSc (University of Botswana)
in May 2008

for the Degree of Doctor of Philosophy
in the School of Mathematical and Physical Sciences
James Cook University
STATEMENT OF ACCESS TO THESIS

I, the undersigned, author of this work, understand that James Cook University will make this thesis available for use within the University Library and, via the Australian Digital Theses network, for use elsewhere.

I understand that as unpublished work, a thesis has a significant amount of protection under the Copy Right and;

I do not wish to place any further restriction on access to this work

STATEMENT OF SOURCES

DECLARATION

I declare that this thesis is my own work and has not been submitted in any form for another degree or diploma at any university other institution of tertiary education. Information derived from the published or unpublished work of other has been acknowledged in the text and a list of references is given.

STATEMENT OF CONTRIBUTION OF OTHERS

Financial contributions toward this PhD thesis were from;

- University of Botswana Staff Development Office,
- Emergency Management Australia Funding Under Project 2001/6001, and
- James Cook University.

There were some general contributions towards this PhD thesis in form of:

- Access to use of Network Analyser equipment from James Cook University’s Electrical and Electronic Engineering Department (Chapter 6).
- Access to take sugar cane fire radio wave propagation measurements at Burdekin Agricultural College in Clare (Chapter 5).
- Access to take radio wave propagation measurements in a controlled grass fire at plot B from James cook University fire officers (Chapter 4)

There was a continual normal supervision and guidance from Prof. Malcolm Lewis Heron and Dr Peter Ridd throughout this PhD thesis.
ACKNOWLEDGEMENTS

I thank my supervisors Prof. Malcolm. Heron and Dr. Peter Ridd for the guidance they have given me throughout this work. Many thanks to Prof. Mal Heron for his never-ending patience and guidance with enthusiasm he provided to the end of this work. My sincere thanks to friends Drs Jonathan Bathgate and Audi Susilo for the encouragement they gave me during the research project.

I sincerely extent my gratitude to the University of Botswana Staff Development Office and Emergency Management Australia (EMA) for the funding they provided for the research. Also, my sincere thanks go to members of the Physics and Electrical and Electronic Engineering Departments of the James Cook University for providing necessary equipment for the research, especially help provided by Drs Graham Woods and Mohan Jacobs and Mr. Ray Casey.
ABSTRACT

Australian vegetation is fire-prone. Every year, wet and dry sclerophyll forests of Western Australia, southeastern Australia and grassland ecosystems of the northern part of the continent are subject to high intensity fires. The sclerophyll vegetation contains up to 2.71% of the element potassium. The element exists in plants’ organic matrix: attached to the oxygen-containing and carboxyl functional groups; in aqueous form such as potassium (K⁺) ions surrounded by water; and as discrete particles in dried plant parts. Theoretically, temperature in the conflagrations can be as high as 2000°C. During the high intensity bushfires, potassium atoms and salts are released from the plant structure as it crumbles into the combustion zone where the species are ionized. Up to 20% of the potassium present in plants is ionized in a bushfire environment.

During suppression of the threat, high frequency (HF) - ultra high frequency (UHF) radio communications systems are in constant use by suppression crews in firegrounds. Despite their use, HF and very high frequency (VHF) radio communications are reported to be failing in extreme bushfire conditions. The reports of radio communication failure tend to be anecdotal and therefore warrant an investigation. This study aims at carrying out field and laboratory radio wave attenuation and phase shift measurements at HF to X-band frequencies in moderate intensity fires. Very high intensity bushfires often spread very fast and change direction rapidly therefore it is unsafe to set up equipment for measuring attenuation and phase shift in the fires. Consequently, numerical experiments were used to study radio wave propagation in very high intensity fires.

Propagation measurement data at radio wave (HF-VHF) frequencies through fire are scarce and that which is available lacks precision. It is also the purpose of the study to produce attenuation and phase measurement data at these frequencies. The field and laboratory measurements were carried out using a Radio Wave Interferometer (RWI) and Vector Network Analyzer (VNA - HP 8277C). RWI uses the same principles as Microwave interferometer (MWI) except that RWI works at radio frequencies. Electron density and momentum transfer collision frequency in moderate intensity bushfire plumes were estimated from the attenuation and phase shift measurements.
Laboratory and field measurements using a VNA - HP 8277C and RWI respectively in moderate intensity fires (700-1000 K) have revealed that electron density in the plume could range from $10^{14}$-$10^{16}$ m$^{-3}$. Theoretical calculations based on local thermal equilibrium in grassfires flames with temperatures up to 1200 K suggest that electron density could be up to $10^{17}$ m$^{-3}$ if up to 20% of the inherent potassium atoms are ionized.

There are at least two possible mechanisms that could lead to a significant signal strength reduction (attenuation) in bushfire environments. They are signal refraction due to thermal bubble and ionization-induced signal absorption in the plume. Electrons, which result from thermal ionization of potassium in the fire, transfer energy from the incident radio wave to the fire plume through collision with inherent neutral particles. The transfer of energy can significantly attenuate and induce a phase shift on radio wave signals. Experimental work carried out in the project suggest that radio wave attenuation is significantly higher at UHF and X-Band frequencies than at HF. Field radio wave propagation measurements at 1.50 m above the seat of a moderate intensity grassfire revealed that 30 MHz signals can be attenuated by up to 0.03 dB/m while 151.3 MHz signals were attenuated by up to 0.05 dB/m. An intense cane fire attenuated 151.3 MHz signals by 0.05 dB/m. The attenuation effect was observed to increase when X-band (10.0 -12.5 GHz) signals were considered. Attenuation coefficients up to 4.45 dB/m were measured.

Phase shift induced on the signals was also observed to increase with the increase in frequency band (low for HF and high for X-band). A 30 MHz signal suffered a 3.08º phase shift in the moderate intensity grassfire whereas in the X-band frequencies, a phase shift of up to 29.31º was observed in a fire of about the same intensity.

Numerical experiments have shown that signal loss due to refraction is frequency dependent in very hot regions of bushfire plumes. X-band waves are more affected than VHF waves. Numerical experiments predicted maximum attenuation coefficients of 0.11 dBm$^{-1}$ for 150 MHz and 0.31 dBm$^{-1}$ for 3 GHz radio waves when they propagate about a meter above fuel-flame interface of a 90 MWm$^{-1}$ bushfire with fuel potassium content of 0.50 %. Theoretical studies also revealed that; for potassium content of about 0.20 %, a collimated beam of radio signals (10 cm wide) propagating at grazing angles to the fuel-flame interface of a very high intensity bushfire (1600 K) could suffer attenuation coefficients of about 1.45 dBm$^{-1}$. This effect is calculated to decrease with the increase in height above the combustion zone. For very high intensity bushfires in fuels with high potassium content (e.g., up to 3.00 %), attenuation by refraction is likely to be...
the most significant form of radio wave energy loss for collimated beams propagating at grazing
angles to the fuel-flame interface.

The Line-Of-Sight (LOS) radio wave propagation measurements in moderate intensity vegetation
fires (700-1000 K) have shown that signal attenuation is plume temperature and frequency
dependent. Transmission through hottest region of the fire (combustion zone) suffers significant
signal strength loss whereas low attenuation has been observed at cooler regions of the plume.
This could be explained by the fact that “collisional plasma effect” on radio waves is more
pronounced at combustion zone than at the thermal plume region of the fire as the effect is
temperature dependent.

Bcontinent with a potential combustion zone temperature of 2000°C. These bushfires have a
potential to adversely affect LOS radio wave communications when transmission is through the
hottest part of the fire. It must be noted that radio wave communication blackout could even
occur at temperatures as low as 1300 K provided that the fire is sufficiently ionized.

Chapter 2: Mechanisms of alkali emissions from vegetation during very high intensity bushfires

2.1. Introduction

2.2. Very high intensity bushfires in regions of Australia

2.2.1. Very high intensity bushfires in southwest Western Australia

2.2.2. Very high intensity bushfires in northern Australian savannas

2.2.3. Very high intensity bushfires in southeastern Australia forests

2.2.4. Very high intensity bushfires in southern Australian heath and shrub lands

2.3. Alkali content in Australian fire-prone vegetation

2.3.1. Chemical composition of plant matter

2.3.2. Alkalis content in plants

2.3.2.1. Availability of alkalis elements to plants

2.3.2.2. Functions of alkali and alkaline earth elements in plants

2.3.3. Alkali and alkaline earth elements content in Australian fire-prone vegetation

2.3.3.1. Alkali and alkaline earth element content in eucalyptus forests of southwest Western Australia

2.3.3.2. Alkali content in eucalyptus forest of southeastern Australia

2.3.3.3. Alkali content in pine species of southeastern Australia

2.3.3.4. Alkali content in understorey vegetation of Australian tropical savannas

2.4. Mode of existence of alkali and alkaline-earth elements in plants
2.5. Mechanisms of alkali release during bushfires ........................................ 34

2.5.1. Chemistry of bushfires ................................................................. 36

2.5.2. Phases of plant combustion ......................................................... 36
