**THE SEDIMENTARY, HYDRODYNAMIC AND TURBIDITY
REGIMES AT INNER-SHELF CORAL REEFS, HALIFAX BAY,
CENTRAL GREAT BARRIER REEF, AUSTRALIA.**

Thesis submitted by

ANDREW RICHARD COSTEN BSc (JCU)

June 1996

*in partial fulfilment of the requirements for the degree of
Bachelor of Science with Honours in Geology
in the Department of Earth Science
James Cook University of North Queensland*

STATEMENT OF ACCESS

I, the undersigned, the author of this thesis, understand that James Cook University of North Queensland will make it available for use within the University Library and, by microfilm or other means, allow access to users in other approved libraries. All users consulting this thesis will have to sign the following statement:

In consulting this thesis I agree not to copy or closely paraphrase it in whole or in part without the written consent of the author; and to make proper public written acknowledgement for any assistance which I have obtained from it.

Beyond this, I do not wish to place any restriction on access to this thesis.

ANDREW COSTEN

**STATEMENT ON SOURCES
DECLARATION**

I declare that this thesis is my own work and has not been submitted in any form for another degree or diploma at any university or other institution of tertiary education. Information derived from the published or unpublished work of others has been acknowledged in the text and a list of references is given.

ANDREW COSTEN

ACKNOWLEDGEMENTS

I would firstly like to thank my supervisors Ken Woolfe and Piers Larcombe for their patient reading and critical comments on all drafts. Thanks goes to Richard Purdon, Stu Watson Kevin Hooper, Paul Giveny and the crew of the *James Kirby* for invaluable assistance with the field work in sometimes difficult conditions. Thanks goes to Chris cuff who helped me with all things chemical, Peter Ridd for his assistance with the machines that went ping, Sonya and Chris for help with “Mal” and Charlotte Morgan for improving my artistic ability. The CRC Reef Research Centre is gratefully acknowledged for their financial assistance.

I would like to thank all of my friends during this year of intellectual torment for the good times and the trips to the club which kept us all sane. I would especially like to thank Aaron Gorrie (Gordy) who also endured honours and my company for nearly five years while at JCU, thanks mate!.

Last but by no means least my deepest thanks go to my parents Anne and Richard and my sisters Tracey and Cris who have always managed to be there for me during my university career. What I have achieved would not have been possible without them, thanks guys.

ABSTRACT

Taxonomic, seismic, vibrocore stratigraphy, surficial sedimentology, turbidity and hydrodynamic data were collected from Paluma Shoals and Phillips Reef. Paluma Shoals are a series of five near-shore patch reefs located within the inner-shelf terrestrial sediment wedge of southern Halifax Bay. Phillips Reef is an isolated patch reef located approximately 15 km northeast of Paluma Shoals. These data sets were collected to compare and contrast the sedimentary, hydrodynamic and turbidity regimes at both Paluma Shoals and Phillips Reef.

The taxonomic survey (Watson, 1996) of Paluma Shoals indicated that total coral cover on the leeward reef flat ($53.4\pm 3\%$) was almost twice that of the windward reef flat ($27.9\pm 3.3\%$). The presence of juveniles was also detected at both the leeward and windward reef flats. The presence of juveniles ($<5\text{cm}$) suggests that coral recruitment is occurring. The taxonomic survey suggests that the corals at Paluma Shoals are a healthy diverse population.

From 79 km of high resolution seismic images, eight seismic facies were identified within the study area. These facies are consistent with those identified by previous investigations. Seven vibrocores were collected to ground truth the seismic profiles. Four postglacial facies were identified on the basis of grain size, stratigraphic relationship and mineralogy.

A total of 135 surficial sediment samples were collected from the study area. Based upon field and laboratory observations and high-resolution laser diffraction grain size analysis, the study area has been divided into, two marine inner-shelf and four coastal facies assemblages.

Entropy analysis of grain size distributions from 58 inner-shelf and coastal sediment samples resulted in statistical clusters which were visually discrete. Seven entropy groups were defined and high resolution grain size maps compiled. High resolution grain size mapping of the inner-shelf of Halifax Bay was successful in producing a map which mirrored the distribution of the surficial sediment facies assemblage.

A total of 1340 hours of continuous high resolution time-series hydrodynamic and turbidity data were recorded at Paluma Shoals (671 hours) and Phillips Reef (669 hours) between Julian days 248 and 276 (1995). Maximum turbidity values were an order of magnitude greater at Paluma Shoals (175 NTU) than Phillips Reef (15 NTU) and generally were higher. The hydrodynamic and turbidity data suggest that Paluma Shoals and Phillips Reef are influenced by the same regional hydrodynamic processes. The surficial sediment seaward of Paluma Shoals are predominantly muddy sand, sandy mud and gravelly muddy sand and on the reef top, muddy sand and sandy mud. Therefore, there is a large source of fine grained sediment available for resuspension. The surficial sediments surrounding Phillips Reef are mostly gravelly muddy sand. Therefore, there is less fine grained sediment available for mobilisation.

The variations in near bed turbidity values at Paluma Shoals and Phillips Reef appear to be a function of local surficial sediment distribution, wind direction and hydrodynamics. At Paluma Shoals the complex interaction between these processes results in high turbidity values but limited sediment settling. At Phillips Reef the limited sediment resuspension and transport (low NTU values) may be attributed to the reefs depth and coarse grained nature of the surface sediments.

Three main implications arose from the collection and collation of these data sets, these are: 1) The corals at Paluma Shoals exist in water conditions widely inferred within the literature as being detrimental to coral growth and distribution; 2) "turbid water reefs" such as Paluma Shoals are potentially common and are healthy diverse populations; 3) during coral reef initiation (c.a. 6.8 ky B.P.) sediment dynamic, hydrodynamic and therefore turbidity regimes may have been similar to those of today. Therefore, "turbid water reefs" may form modern analogues to coral reefs that underwent initiation 8.5-5ky B.P.
