Abstract

Issue addressed: Primary healthcare settings are important providers of health promotion approaches. However, organisational challenges can affect their capacity to deliver these approaches. This review identified the common enablers and barriers health organisations faced and it aimed to explore the experiences health organisations, in particular Aboriginal organisations, had when increasing their health promotion capacity.

Methods: A systematic search of peer-reviewed literature was conducted. Articles published between 1990–2014 that focused on a health care–settings approach and discussed factors that facilitated or hindered an organisation’s ability to increase health promotion capacity were included.

Results: Twenty-five articles met the inclusion criteria. Qualitative (n = 18) and quantitative (n = 7) study designs were included. Only one article described the experiences of an Aboriginal health organisation. Enablers included: management support, skilled staff, provision of external support to the organisation, committed staffing and financial resources, leadership and the availability of external partners to work with. Barriers included: lack of management support, lack of dedicated health promotion staff, staff lacking skills or confidence, competing priorities and a lack of time and resources allocated to health promotion activities.

Conclusions: While the literature highlighted the importance of health promotion work, barriers can limit the delivery of health promotion approaches within primary healthcare organisations. A gap in the literature exists about how Aboriginal health organisations face these challenges.

So what? Primary healthcare organisations wanting to increase their health promotion capacity can pre-empt the common barriers and strengthen identified enablers through the shared learnings outlined in this review.

Received 8 July 2015, accepted 7 January 2016, published online 20 April 2016

Introduction

Health promotion plays an important role in maintaining and improving the overall health of the population. Health promotion is defined as “the process of enabling people to increase control over their health and its determinants, and thereby improve their health”¹. Approaches that are multi-strategic and guided by the Ottawa Charter for Health Promotion¹ have been effective in improving healthy lifestyle behaviours and in reducing the risk of developing non-communicable diseases.² By specifically improving diet, physical activity levels and eliminating tobacco smoking it is estimated at least 80 per cent of all heart disease, stroke and type 2 diabetes and over 40 per cent of cancer would be prevented.²

An individual’s health is determined not only by their behaviours but also by their circumstances and environment.³ Health promotion approaches focus on strengthening the skills and capabilities of individuals, groups and the broader population as well as influencing the social, environmental and economic determinants of health.¹ To address the environmental, social and economic determinants, health promotion approaches are implemented across several organisational settings both within and outside of the health sector. Health services are recognised by the World Health Organization as a key setting for health promotion and include hospitals, primary health care, community health and public health organisations.⁴ Primary healthcare organisations are important providers of health promotion approaches. They are the first point of contact for individuals, families and the community with the healthcare system.⁵ Four out of five Australians will see a primary healthcare professional at least once a year.⁶ The links between health promotion and
Primary health care were defined in the Declaration of Alma-Ata. Primary health care is a key setting for the promotion of healthy behaviours, identification of risk factors for ill health and the treatment of illness.

In Australia, the health status and life expectancy of Aboriginal and Torres Strait Islander peoples is much lower than that of the general population. The higher mortality rates for preventable chronic diseases is well documented. In response to this health inequity, Aboriginal community controlled health services (ACCHS) emerged in the early 1970s to improve access and provide culturally appropriate health care. ACCHS are primary healthcare organisations that provide holistic, comprehensive and culturally appropriate health care, planned and managed by boards elected from the local Aboriginal community. The philosophy of community control is consistent with health promotion theory, which states that the health status of Aboriginal people can only be improved by local Aboriginal people controlling healthcare delivery in their community.

Both mainstream primary healthcare services and ACCHS face many known challenges in the delivery of health promotion. Short-term funding cycles, lack of commitment to long-term evaluations, inconsistencies in practices, and the contested meanings of health promotion by decision makers continue to hinder the effective implementation of health promotion approaches. Additionally, managing both treatment and health promotion roles can be challenging for primary healthcare providers. The broader health promotion role may be neglected if an individualistic approach that focuses solely on the immediate treatment needs of the client is taken. This individualistic approach to health care and emphasis on health education alone may influence decision makers within the health service to prioritise short-term targets of health care at the expense of long-term targets that support improved health outcomes.

With the emergence of health-promoting healthcare settings in the 1990s, health promotion practitioners have focused on building health promotion capacity through infrastructure that includes staff, skills, resources and workplace structures to address health problems more effectively. Others have focused on building capacity to sustain the effects of health promotion programs and build problem-solving capacity through partnerships at an individual, community and organisation level to better address health problems. Work done by Hawe and colleagues, and later supported by Judd and Keleher, identified specific organisational structures and processes that can strengthen health promotion capacity within an organisation. Organisations need workforce capability, organisational support through resource allocation and collaborative approaches, and structures to utilise opportunities and skill sets to deliver effective health promotion approaches. Systems thinking linked with change processes have been used at organisational levels to identify system supports and influencing mechanisms such as policies, inter-relationships, resources and organisational values. The health promotion capacity building framework identifies five key components required to build capacity: organisational development, workforce development, resource allocation, leadership and partnerships. The framework acknowledges the interdependency between the components and has guided health promotion capacity building work, particularly in Australia, since the early 2000s. The health promotion capacity building framework identified areas that can be strengthened to embed health promotion within an organisation. However, when reorienting health services it is important to understand the challenges of implementing change into practice. This review aimed to identify the common enablers and barriers these organisations face and to explore the experiences health organisations, in particular Aboriginal and Torres Strait Islander organisations, had when increasing their health promotion capacity.

**Methods**

A systematic search of peer-reviewed articles was conducted using electronic databases including APAIS, APAFT, CINAHL, Current Contents Connect, Medline, ProQuest Central, PsycARTICLES, PsycINFO, Scopus, Social Sciences Citation Index, the Cochrane library, Google Scholar and the Australian Indigenous Health Infonet. Further articles were sourced from hand searching of reference lists from articles identified through the database search. Search terms (MeSH and text words) were defined by the outcome of interest ‘health promotion’; the change effect which included terms such as ‘capacity building’, ‘organisational innovation’, ‘organisational change’ and ‘organisational development’; and the health organisational setting using terms such as ‘primary health care’, ‘public health administration’ and ‘community health services’. Given the particular interest in exploring health promotion in Indigenous healthcare settings, ‘Indigenous’ and ‘Aboriginal’ and Torres Strait Islander’ search terms were also used. However, no relevant articles were found. The Australian Indigenous Health Infonet database was then searched and one relevant article was found. Only articles published in English between 1990 and March 2014 were included. The rationale for the start year was that health promoting health settings were first discussed in the early 1990s. The dates of publication for articles in the full text review ranged from 1992 to 2014. To ensure articles described enablers and/or barriers for building organisational health promotion capacity within a health organisation were found, articles were only included if they focused on a health care–settings approach and discussed the factors that facilitated or hindered an organisation’s ability to increase their health promotion capacity. Both qualitative and quantitative studies were included to obtain a broader understanding of this area.

Articles were excluded if: (i) health promotion capacity was aimed at collectively increasing a coalition’s or group of partner
organisations ability to undertake a combined health promotion approach; or (ii) the content was general in nature and an organisation’s experiences were not used as examples of how health promotion capacity was affected.

Titles and abstracts were independently reviewed for topic relevance. Four hundred and sixty-five articles were found. After the removal of duplicates (n = 340) a total of 125 articles were then reviewed for relevance. Following a full-text review, 100 articles were excluded, leaving 25 relevant articles to be included in the review. Figure 1 summarises the article selection process.

Results

Twenty-five articles met the inclusion criteria. These articles described health promotion capacity building initiatives in Australia, Canada, United States of America, Africa, China, United Kingdom, Sweden and the Solomon Islands, with the majority of papers from Australia (n = 8) and Canada (n = 8). The organisational settings included primary health care, community health, hospitals and public health organisations. Table 1 summarises the studies discussed in this review.

There were three main ways the articles identified the enablers and barriers to increasing health promotion capacity. First, health organisations implemented specific capacity building interventions, such as workforce training and leadership development, and assessed the enablers and barriers when implementing these interventions. Second, health organisations implemented a new program in their organisation and included in their evaluation the impact of organisational enablers or barriers. Lastly, articles reported on what the health promotion workforce perceived were the enablers and barriers to health promotion practice. Across all studies common themes were identified.

Enablers for increasing health promotion capacity within health care organisations

To increase organisational health promotion capacity, management support,18,20–33 a skilled and knowledgeable workforce,34–38 external specialist assistance,18,24,32,34,35 resource allocation,20,22,27,31 leadership,26,27,29,31,33,35,40 and access to external partners to work on health promotion approaches21,25–27 were the most commonly reported enablers. Management support was reported in two ways: first, the line manager’s influence on work practice; and second, the influence of the organisation’s ethos and practice. Key features of these enablers are outlined in Table 2.

Barriers to increasing health promotion capacity within healthcare organisations

The most common reported barriers for an organisation aiming to increase health promotion capacity were: lack of management support,20,26,37,38 lack of dedicated health promotion staff,25,26,30,41

| Barrett et al. (2007)<sup>40</sup> | To examine organisational leadership and its relationship to organisational action to promote health.                                                                               | Convenience sample of representatives from regional health authorities. Alberta, Canada (n = 144)                                                                                                                        | **Design:** Analytical cross-sectional study                                                                 | (1) Perceived collective organisational leadership including: practices for organisational learning; wellness planning; workplace milieu; and organisation member development.  
(2) The relationships of the organisational leadership components with organisational actions.  
19 dependent variables were grouped into three areas: health promotion; heart health promotion; and global outcomes that were aggregated scores for settings, activities and actions on the heart health determinants model. | Practices for organisational learning and wellness planning were significantly, positively associated with the outcome variables. Organisation member development had a significant positive association with health promotion implementation.  
**Enablers:** organisational learning, wellness planning and the presence of a champion for heart health promotion had the greatest relationship with health promotion actions. Health promotion actions included: assessment; implementation on Ottawa Charter action strategies for health promotion; and evaluation. | Focus on organisational leadership only. Authors stated values were significant but did not provide p-values.  
Selection bias may be present due to volunteer and recall bias.  
The study may not be generalisable to other organisations outside of regional health authorities in Alberta. |
| Devine et al. (2009)<sup>37</sup> | The effect of health promotion workforce training on longer term practice. Evaluation at conclusion of course and 6 months later. | Health service staff who attended the 5-day short course. Queensland, Australia (n = 39 out of 54)                                                                                                                        | **Design:** Pre test–post test  
**Data collection:** Self-report postal survey, focus group and phone interviews | Perceived opportunities and barriers for participants to undertake health promotion in their work environment and whether there was organisational support to do so following the training course in health promotion. | **Barriers:** No significant associations were reported. However the qualitative data indicated the following barriers: management support; mentoring for new or inexperienced health promotion workers; lack of time; lack of internal funding; health promotion was not incorporated into overall strategic planning; lack of understanding from co-workers and managers; lack of organisational support and commitment; lack of resources, and competing clinical priorities. | Focus on workforce development only. Selection bias may be present with those who volunteered to be in the post test comprising 39 of the 54 possible respondents. |
Guo et al. (2007) To identify the attitudes of managers involved in health promoting hospitals.

Managerial employees from selected health promoting and control hospitals, Beijing, China (n = 106 hospitals; n = 281 managerial employees)

Design: Analytical cross-sectional study
Data collection: Face-to-face interviews

Effectiveness of health promoting hospital implementation included: long-term planning of health promotion; specialised funding for health promotion; training for medical staff; training skills in health promotion; provision of health education for patients by professionals. Managerial perspectives were measured for: understanding of health promoting hospitals; attitude about need for health promotion in hospitals; and achievements and barriers for health promotion in hospitals.

Significant positive association with health promotion hospital implementation when long-term planning and specialised funds for health promotion were allocated (OR 12.05 (95% CI: 1.48–97.91) and 2.71 (95% CI: 0.79–9.29) respectively).

Enablers: commitment to health promotion evidenced through long-term planning and identified funding; and knowledge and understanding of the concept health promoting hospitals.

Barriers: shortages of funds, personnel, time management and professional skills.

Kardakis et al. (2014) To investigate health professional work with lifestyle interventions in primary health care and describe the knowledge, attitudes and organisational support that is available.

Purposive sampling of nurses and physicians in primary health care, Sweden (n = 315)

Design: Descriptive cross-sectional study
Data collection: Web-based questionnaire

Attitudes and knowledge of lifestyle interventions; extent to which professionals and primary healthcare centres work with patient lifestyles; and perceived organisational support. A 5-point Likert scale was used to quantify responses (item responses ranged from ‘completely disagree’ to ‘completely agree’).

78% of professionals perceived a need for national guidelines for lifestyle interventions and this was statistically significant between professional groups. (P < 0.05)

Enablers: management support and local guidelines to guide work with the promotion of healthy lifestyles.

Panaretto et al. (2010) To report on the organisational capacity to perform opportunistic BIs for SNAP risk factors.

Clinical staff (Aboriginal Health Workers, nurses, doctors and practice managers) at 4 urban Aboriginal and Torres Strait Islander medical services, Queensland, Australia (n = 46)

Design: Analytical cross-sectional study; case series; focus groups
Data collection: Self-administered survey, medical chart audit and focus groups

Survey: knowledge and attitudes pertaining to BI, screening tools available, frequency of BI, availability and use of referral services and provision of training. Medical chart audit: risk assessment of SNAP, delivery of BI and completion of key clinical indices. Focus groups: enablers and barriers to the delivery of BI including the role of the workforce, information technology, management support, past training and perceived support needs.

Significant difference in the participating clinics for conducting risk assessments and brief interventions in smoking, nutrition, alcohol and physical activity than comparison clinics (P < 0.001)

Enablers: time available with clients and the adult health check screening process prompted brief interventions.

Barriers: inflexible staff training, lack of confidence of staff to conduct brief intervention, competing health priorities and high levels of staff turnover.

Confidence intervals are wide. Confounding bias may be present. Results may not be generalisable outside of Beijing hospital settings.

Study may not be generalisable outside of Swedish primary healthcare organisations. Selection bias may be present due to volunteer bias of those that completed the web-based questionnaire.

Focus was on the delivery of brief interventions by the organisations only. Selection bias may be present due to volunteer bias of those that completed the survey and participated in the focus groups.

| Tang et al. (2005)\(^24\) | To describe the development and implementation of the project and the impact of the technical assistance project. | Convenience sample of participants in the training, key stakeholders of the project. China \((n = 219)\) | **Design:** Pre test–post test  
**Data collection:** Self-administered questionnaires, annual reports | Participants’ perceived changes to organisational support and capacity measured through 8 domains: leadership, expertise, structure, reward, helpful mechanisms, relationships, purpose and attitude to change. Evidence of policy, strategy and guideline development in annual reports. Evidence of improved project management in project proposals and project reports. | Significant improvement as a result of the training in all of the domains \((P < 0.0001)\)  
**Enablers:** technical assistance providing training in health promotion (knowledge and skill application); support from political leaders and senior managers; and consultant expertise in health promotion and in developing a respectful working relationship. | There may have been other external influences of organisational practice in health promotion in China at this time. Difficult to attribute change to this intervention only without a comparison group. Selection bias may be present due to volunteer bias of those that completed the survey and recall bias over the 3-year period. |

| Van den Broucke et al. (2010)\(^28\) | Three objectives: to integrate health promotion into the health policy plans at the national, provincial and district level; strengthen health promotion capacity in two provinces; and support the development of tools for the monitoring and evaluation of health promotion. | Identified participants in the health promotion projects and stakeholders. South Africa \((n = 58)\) | **Design:** Pre test–post test  
**Data collection:** Document analysis, site visit, focus groups and face-to-face interviews. | Stakeholder participation in activities and perceived quality and usefulness of the project activities through project documents and interviews. Increase in health promotion capacity was scored using the CCI to measure indicators on a 5-point scale (substantial decrease, small decrease, no change, small increase, substantial increase), in the domains of: partnerships, knowledge transfer, problem solving and infrastructure. | A substantial increase in capacity was found for two of the CCI domains as scored by the external evaluator based on focus group data: (i) network partnerships, capacity to identify the organisations and groups with resources to implement/sustain a health promotion program; and (ii) knowledge transfer, capacity to develop a health promotion program that meets the needs of the community.  
**Enablers:** health promotion recommendations in strategic planning documents; ability to identify the organisations and groups with resources to partner with; skills and knowledge to develop and implement health promotion programs.  
**Barriers:** policy makers focused on cure rather than health promotion. | There may be selection bias from volunteers who participated in the focus groups and interviews. Study findings may not be generalisable outside of this context of an external country (Belgium) and the WHO providing support to South Africa. |

financial and policy environments.

Wills and Rudolph (2010) To report on a training program aimed at developing capacity and capability of health promoters.

Health promotion students. South Africa (n = 20)

Design: Qualitative Data collection: Semi-structured interviews

Acquisition of knowledge and skills; subsequent application of new knowledge; and its impact on the organisation and their role in the organisation.

Enablers: training increased perceived knowledge and confidence to practice health promotion; staff had clarity of what health promotion is and confidence to describe health promotion practice in their workplace.

Barriers: lack of management support to change practice; manager’s expectations and understanding of health promotion in conflict to new understanding of staff after the training; and disease-orientated healthcare system where health promotion workers were seen as less important than clinical staff.

The interviews were conducted at the completion of the course, with little time for application into their organisational setting.

Yeatman and Nove (2002) To describe the actions aimed at building organisational support for health promotion.

Senior and middle managers, and service delivery staff New South Wales, Australia (n = 23)

Design: PAR/qualitative Data collection: Document analysis of written reports, semi-structured interviews and focus groups

Managers perspectives of the training course and the implementation of the learnings in the workplace; application of workplace changes in comparison to the recommendations; and participants perceptions of the implementation of the recommendations and their knowledge of the new structures introduced.

Enablers: leadership that maintains focus overtime as well as motivates and supports staff; partnerships internally and externally (funding body and academic); and building, demonstrating and maintaining commitment over the long term.

Barriers: lack of recognition for health promotion activities within the organisation; lack of management support; lack of resources; difficulties in getting health promotion initiatives to be considered priorities; variable quality of health promotion work; and lack of higher level skills training in health promotion.

Describes the experiences of one regional health service in NSW. Difficult to attribute change to this intervention only without a comparison group.

---

*Sampling process is described for those articles where it was explicitly stated.

* A limitation of all cross-sectional studies is that the direction of association cannot be determined. Cross-sectional studies were conducted by Barrett et al. (2007), Guo et al. (2007), Kardakis et al. (2014) and Panaretto et al. (2010).
staff who lacked skills or confidence in health promotion, competing priorities, and a lack of time and resources allocated to health promotion activities. A summary of these barriers is presented in Table 3.

Discussion

This literature review has demonstrated that, very few studies have comprehensively reviewed building health promotion capacity within a health organisation. Most of the included studies focused on specific areas such as training for the workforce, leadership development or delivery by staff of a new health promotion program. The majority of the articles (n = 15) referenced the work of Hawe and colleagues and/or the NSW Health Department capacity building framework for health promotion to guide their interventions. Interestingly, all enablers and barriers identified in the 25 articles reflected at least one of the five areas of this framework (organisational development, workforce development, resource allocation, leadership and partnerships).

There was consistency in the literature regarding the importance of health promotion work in improving overall health outcomes and the challenges faced by health organisations to achieve this. Many authors acknowledged the challenges of the political environment, through changing priorities, access to resources and long-term funding.

Only one study related to an Indigenous health service. This study examined the organisation’s capacity to conduct brief interventions with clients. The enablers and barriers identified were consistent with other studies in this review. Brief intervention by itself is a single strategy health promotion approach. The narrow focus of evaluating a single strategy, and that only one study was found, highlights the limited knowledge in this area. Further and more comprehensive research is required to understand the enablers and barriers to increasing health promotion capacity in Indigenous health organisations.

Methodological limitations were present in all of the studies identified in this review. Many studies included a small sample size (less than 25 participants), and selection bias was present in most studies. This is particularly relevant for quantitative studies. Selection bias is expected in qualitative research designs due to purposive sampling, which was required here to ensure those involved in health promotion approaches were included in sharing their experiences. With these limitations the findings may only be generalisable to the relevant organisational context. However, the enablers and barriers identified were common across the studies and despite these limitations there are several key findings that
can be explored further: management support, leadership, external specialist assistance, skilled staff, partnership work, resource allocation, and the challenge of competing work priorities in health organisations.

Management support was the most commonly reported enabler and barrier. Management support was often referred to as the line manager’s role. Managers are leaders for the direction of the work team and translate strategic direction and policies into activity. However, their influence is limited by organisational constraints such as political agendas, funding and reporting requirements. Organisational policies supportive of health promotion practice can limit the influence of these constraints.

Only a few studies identified managers’ perspectives on the enablers and barriers to health promotion capacity.26,30,33 The majority of studies reported the enablers and barriers from a practitioner’s point of view.18,21–25,33,37,38 As managers were identified as gatekeepers to many of the enablers and barriers to health promotion practice within an organisation, further exploration of the supports required to assist the management role would be useful.

Managers were identified as crucial for providing leadership within the organisation about health promotion practice. The ability to assess readiness for change and to motivate and support new ways of working was identified as an important leadership skill.26,29,33 Additionally, staff who model good health promotion practice can lead a change in practice throughout the organisation,33 demonstrating that the influence of leadership in this process is not solely the responsibility of managers.

There were several interventions where external specialist assistance was provided and valued by the participants when evaluated.18,24,32–35 Access to expertise outside the organisation during and after the change process was important. One-off, short-term assistance such as training would not embed the skills and systems learned without support to translate this into practice.

A skilled workforce is essential for effective health promotion practice.21 This was identified in studies that addressed the need to improve knowledge and skills through training and by practitioners who identified that health promotion knowledge and skills were required to effectively deliver health promotion approaches.25,29,36,40,42 While this finding is not necessarily surprising, the frequency with which it was mentioned in the studies highlights its importance.

Partnerships can achieve greater health outcomes than an individual organisation can do on its own. Working in partnership combines resources and expertise to address a health issue of concern. A practitioner’s skills in partnering with external stakeholders, and the organisation’s ability to work in partnership, increases the organisation’s own health promotion capacity.21,25–27 For partnership to occur there needs to be openness and commitment from the organisation to allow staff to build robust relationships.

The strength of an organisation’s commitment to health promotion can be measured through its allocation of resources. This includes dedicated staff to work on health promotion programs and financial support for resources needed to develop, deliver and evaluate health promotion programs. In an environment where additional funds for prevention work are not available, understanding how best to utilise existing resources is essential.

Influencing quality improvement processes to support health promotion practice can increase an organisation’s health promotion capacity.24,29,32,33 The process of adhering to and reflecting on practice through quality improvement reviews can be a driver for improving practice where incremental standards for health promotion practice have been articulated. Continuous quality improvement processes have been used effectively to sustain improvements in Aboriginal and Torres Strait Islander primary health care settings.44,45 Combining this with a focus to assess health promotion practice has been shown to build an organisation’s confidence in identifying health promotion improvement strategies.
and actions.\textsuperscript{46} Further work is underway to assess how this confidence will impact on organisational health promotion capacity.\textsuperscript{46}

Many health organisations provide both treatment and health promotion services. If other priorities are deemed more important, a health promotion and prevention focus can be lost.\textsuperscript{38,39,47–49} This could be due to lack of dedicated resources for health promotion approaches, lack of management support, or health promotion not being identified as a priority in the organisation’s strategic focus. In primary healthcare organisations that are clearly involved in both treatment and health promotion work, it would be useful to explore further how this challenge is addressed in a resource-poor environment.

Conclusion

Reorienting health services to increase health promotion capacity requires systematic change within the organisation. The enablers and barriers identified critical parts of the system to target change processes; however, the interdependency between these enablers and barriers was not identified in this literature review. Taking a systems approach to better understand the interdependent relationships between management support, leadership, external specialist assistance, skilled staff, partnership work, resource allocation and competing work priorities may help to better understand how organisational capacity for health promotion can be increased within health service organisations. This is particularly important within Aboriginal and Torres Strait Islander communities where problems are complex and there is strong interconnectedness between the health service and the community.

The literature review identified consistent themes in the enablers and barriers for organisations to increase their health promotion capacity. For health services to deliver both treatment and health promotion functions to the communities they serve, organisational systems need to support managers and practitioners, ensuring there is a skilled health promotion workforce with opportunities to work in partnership. The challenge of competing work priorities will remain. However, health promotion needs to be recognised as a priority and embedded into organisational roles and responsibilities. A supportive policy environment that identifies health promotion as a core part of business will reinforce this within the organisation.

With limited information on how health promotion capacity has been increased in Aboriginal health organisations, the relevance of these findings for ACCHS is not clear. Further research into how ACCHS deliver health promotion, and the identification of enablers that assist practice in that setting, will address this knowledge gap.
