Sensory quality is an important consideration when Singapore consumers purchase pork. They often associate non-Indonesian pork with the presence of an unpleasant off-flavour described as a mutton-like flavour. Some evidence indicates that the intensity of undesirable flavours in meat can be reduced by herbs and spices. The current experiments assessed the possibility of reducing mutton flavour in pork and improving its acceptability by adding garlic oleoresin. The threshold level for aroma of garlic oleoresin when added to rice bran oil or minced pork was determined. For cooked pork mince the threshold for garlic taste was also assessed, along with levels of mutton aroma and taste, and acceptability. Singapore and New Zealand panellists were used.

The concentration at which aroma of garlic oleoresin could be detected by Singaporean (n=50) and New Zealand (n=49) consumers in rice-bran oil, and in either raw or cooked pork mince (n=30 for Singaporean consumers and n=50 for New Zealand consumers) was assessed using a threshold test protocol. Most panellists in Singapore (80%) and New Zealand (75%) could detect garlic aroma in rice bran oil at a concentration of 75 ppm. Increased garlic oleoresin concentration in rice bran oil had a positive influence on garlic aroma intensity (p<0.05) for Singapore and New Zealand panellists, and also on garlic aroma hedonic scores for Singapore consumers only (p<0.05). For cooked pork mince, panellists detected significant differences in garlic (p=0.0001) and mutton (p=0.0001) aroma intensity with increasing levels of garlic oleoresin (0 to 175 ppm), but the degree of liking of garlic aroma did not change significantly. A garlic oleoresin concentration of 100 ppm in pork mince significantly increased the intensity of garlic aroma and reduced the mutton aroma in raw and cooked pork samples. To significantly reduce mutton taste in pork mince, a garlic oleoresin concentration of 125 ppm was needed. Increases in the intensity of garlic aroma and taste were associated with increases in acceptability of cooked-mince garlic taste to a greater extent for Singapore panellists than New Zealand panellists. It is concluded that undesirable mutton-like flavour notes in pork mince may be reduced by adding garlic oleoresin.

MILK YIELD OF HOLSTEIN-FRIESIAN AND JERSEY X HOLSTEIN-FRIESIAN COWS SUPPLEMENTED WITH CANOLA MEAL AND CRACKED LUPINS

Malau-Aduali AEO1, Chiu YF1, Jones D2, Nichols PA1

Milk yield is a key selection trait in dairy cows. During the course of lactation, milk yield follows a typical curvilinear pattern characterized by an initial increase immediately after calving, a rise to peak before an eventual decline. Cows in mid-lactation are typically in the decline phase and would require supplementation to ensure persistency in milk yield, particularly during summer when pasture availability is limited. This study evaluated the milk yield responses of purebred and crossbred dairy cows to two levels (1 or 2 kg/cow/day) of canola meal or cracked-lupins supplementation in a pasture-based production system. Fifty Holstein-Friesian (HF) and Jersey x Holstein-Friesian (JHF) dairy cows (10 unsupplemented control and 40 supplemented) were randomly assigned to treatment groups after balancing for initial milk yield, BCS and days in milk (mean initial milk yield, body weight and body condition scores were 12.5±12.1 litres/d, 352.6±31 kg. and 2.5 respectively). A 2 x 2 x 2 balanced factorial experimental design representing 2 breeds, 2 supplements and 2 feeding levels was utilized. All cows had ad libitum access to the basal diet of barley and ryegrass while supplemented cows had three weeks of adjustment before the 12 weeks of feeding trial commenced. All cows were milked twice daily and milk yield individually recorded automatically at milking. Data were tested for significance by fitting the fixed effects of breed, supplement, feeding level and their first order interactions using mixed model procedures in SAS with cow and days in milk as random effects. Overall differences between treatment means were declared significant at P<0.05. Milk yield at all times was significantly higher in supplemented than unsupplemented cows with the rate of decline in milk yield faster in unsupplemented cows. For ten consecutive weeks, supplementing with lupins elicited a better milk yield response than with canola but breed differences between purebred and crossbred cows were not significant (P>0.26).
